**Definition 1.** A space X is strong Eberlein compact if it embeds in  $\sigma 2^{\kappa} = \{x \in 2^{\kappa} : | \{\alpha : x(\alpha) = 1\}| < \omega\}.$ 

**Theorem 2** (Gruenhage). For compact spaces X, X is strong Eberlein compact if and only if X is scattered and X is a W-space ( $\mathcal{O} \uparrow Gru_{O,P}^{\rightarrow}(X,x)$  for all  $x \in X$ ).

Theorem 3.  $\mathscr{D} \uparrow_{tact} Bell_{D,P}^{\rightarrow} (\sigma 2^{\kappa}).$ 

*Proof.* Let supp $(x) = \{\alpha : x(\alpha) = 1\} \in [\kappa]^{<\omega}$ .

Define the tactic  $\sigma$  for  $\mathscr{D}$  such that

$$\sigma(\langle x \rangle) = \bigcap \{ P_{\alpha}(\Delta) : \alpha \in \text{supp}(x) \}$$

Fix a legal attack  $p: \omega \to \sigma 2^{\kappa}$ , and let  $\alpha < \kappa$ . If  $p_{\alpha}: \omega \to \sigma 2^{\kappa}$  defined by  $p_{\alpha}(n) = p(n)(\alpha)$  converges for each  $\alpha < \kappa$ , then  $\sigma$  is a winning tactic. So assume  $p_{\alpha}(n) = 1$  for some n, and as  $\alpha \in \text{supp}(p(n))$ ,  $\sigma(p(n)) \subseteq P_{\alpha}(\Delta)$ . As p is a legal attack, it follows that  $p_{\alpha}(m) = p_{\alpha}(m+1)$  for all m > n, so  $p_{\alpha}$  converges. Otherwise  $p_{\alpha}(n) = 0$  for all n so  $p_{\alpha}$  converges to 0.

Corollary 4. If X is strong Eberlein compact, then  $\mathscr{D} \uparrow_{tact} Bell_{D,P}^{\rightarrow}(X)$ .

**Theorem 5.** If X contains a copy of the Cantor set, then  $\mathscr{D} \underset{tact}{\gamma} Bell_{D,P}^{\rightarrow}(X)$ .

*Proof.* The result follows from showing that  $\mathscr{D} \underset{\text{tact}}{\uparrow} Bell_{D,P}^{\rightarrow}(2^{\omega})$  (any copy of the Cantor set within a Hausdorff space is a compact and thus closed subspace). Let  $\sigma$  be a tactic for  $\mathscr{D}$  in  $Bell_{D,P}^{\rightarrow}(2^{\omega})$  and let  $D_k = \{\langle f,g \rangle : f \upharpoonright k = g \upharpoonright k\}$ . Since  $\{D_k : k < \omega\}$  is a base for the uniformity on  $2^{\omega}$ , we may fix  $k(f) < \omega$  for each  $f \in 2^{\omega}$  such that  $D_{k(f)} \subseteq \sigma(\langle f \rangle)$ .

Then there exists  $k < \omega$  such that  $\{f : k = k(f)\}$  is uncountable, and therefore there exist distinct f, g such that k = k(f) = k(g) and  $f \upharpoonright k = g \upharpoonright k$ . Then  $p : \omega \to 2^{\omega}$  defined by p(2n) = f and p(2n+1) = g is an attack against  $\sigma$  which obviously doesn't converge. This attack is legal since  $f \in D_k[g] \subseteq \sigma(\langle g \rangle)[g]$  and  $g \in D_k[f] \subseteq \sigma(\langle f \rangle)[f]$ .

**Lemma 6.** Every non-scattered Corson compact space contains a homeomorphic copy of the Cantor set.

*Proof.* Every non-scattered space contains a closed subspace without isolated points. Let X be such a subspace, and assume that this Corson compact is embedded in  $\Sigma \mathbb{R}^{\kappa}$ . Let  $B_{\alpha,\epsilon}(x) = \{y : d(x(\alpha), y(\alpha)) < \epsilon\}$ . For each  $x \in X$  and  $n < \omega$ , let  $\beta(x, n) < \kappa$  be defined such that  $\{\alpha : x(\alpha) \neq 0\} = \{\beta(x, n) : n < \omega\}$ .

Choose an arbitrary  $x_{\emptyset} \in X$  and  $\epsilon_0 > 0$ , and and let  $A_0 = \emptyset$ .

Suppose then that for some  $n < \omega$ ,  $x_s \in X$  is defined for all  $s \in 2^n$ , and  $\epsilon_n > 0$  and  $A_n \in [\kappa]^{<\omega}$  are defined. Since each  $x_s$  is not isolated in X, let  $U_s$  be the open set

$$U_s = X \cap \bigcap_{\alpha \in A_{|s|}} B_{\alpha, \epsilon_{|s|}}(x_s)$$

and choose  $x_{s^{\frown}\langle 0 \rangle}, x_{s^{\frown}\langle 1 \rangle} \in U_s$  distinct. Then let  $\alpha_s < \kappa$  such that  $x_{s^{\frown}\langle 0 \rangle}(\alpha_s) \neq x_{s^{\frown}\langle 1 \rangle}(\alpha_s)$ . Let

$$A_{n+1} = \{\alpha_s : s \in 2^{\le n}\} \cup \{\beta(x_s, i) : s \in 2^{\le n}, i \le n\}$$

Then choose  $0 < \epsilon_{n+1} < \frac{1}{2}\epsilon_n$  such that

$$B_{\alpha_s,\epsilon_{n+1}}(x_s^{\widehat{}}\langle 0\rangle) \cap B_{\alpha_s,\epsilon_{n+1}}(x_s^{\widehat{}}\langle 1\rangle) = \emptyset$$

and

$$\bigcap_{\alpha \in A_{n+1}} B_{\alpha,\epsilon_{n+1}}(x_s \cap \langle 0 \rangle) \cup \bigcap_{\alpha \in A_{n+1}} B_{\alpha,\epsilon_{n+1}}(x_s \cap \langle 1 \rangle) \subseteq \bigcap_{\alpha \in A_n} B_{\alpha,\epsilon_n}(x_s)$$

for all  $s \in 2^n$ .

Let  $x_f = \lim_{n < \omega} x_{f \upharpoonright n} \in X$  for each  $f \in 2^{\omega}$ . We claim  $C = \{x_f : f \in 2^{\omega}\}$  is a copy of the Cantor set. This will follow if we can show that  $\{U_s : s \in 2^{<\omega}\}$  is a base for C, since it has the structure of the Cantor tree.

Consider  $x_f$  for some  $f \in 2^{\omega}$ , and a subbasic open ball  $B_{\alpha,\epsilon}(x_f)$ . Observe that  $x_f \in \bigcap_{n < \omega} U_{f \mid n}$  since  $x_{f \mid n} \in U_{f \mid m}$  for all  $m < n < \omega$ .

If  $\alpha \in \{\beta(x_s, n) : s \in 2^{<\omega}, n < \omega\}$ , choose  $k < \omega$  with  $\alpha \in A_k$ . Then choose  $l < \omega$  such that  $\epsilon_l < \epsilon$ . Then  $U_{f \upharpoonright (l+k)} \subseteq B_{\alpha, \epsilon}(x_f)$ .

Otherwise,  $x_s(\alpha) = 0$  for all  $s \in 2^{<\omega}$ , so  $x_g(\alpha) = 0$  for all  $g \in 2^{\omega}$  and therefore  $C \subseteq B_{\alpha,\epsilon}(x_f)$ .

**Corollary 7.** For compact spaces X, X is strong Eberlein compact if and only if  $\mathscr{D} \uparrow_{tac}$   $Bell_{D,P}^{\rightarrow}(X)$ .

*Proof.* Suppose X is not strong Eberlien compact; then X is either not a W-space or not scattered. If  $\mathscr{D} \not\uparrow Bell_{D,P}^{\rightarrow}(X)$ , then the result follows immediately, which only leaves non-scattered proximal compact spaces to be considered. But non-scattered proximal compacts are non-scattered Corson compacts, and thus contain a copy of the Cantor set, so the result follows from Theorem 5.

**Proposition 8.** If X is completely metrizable, then  $\mathscr{D} \uparrow_{2\text{-tact}} Bell_{D,P}^{\rightarrow}(X)$ .

*Proof.* Let  $\sigma(x,y) = D_{\frac{1}{2}d(x,y)}$ . Then all legal attacks are Cauchy, and thus converge.  $\Box$

 $\textbf{Corollary 9.} \ \ \mathscr{D} \ \ \underset{tact}{\uparrow} \ Bell_{D,P}^{\rightarrow}\left(2^{\omega}\right) \ but \ \mathscr{D} \ \underset{2-tact}{\uparrow} \ Bell_{D,P}^{\rightarrow}\left(2^{\omega}\right) \ and \ \mathscr{D} \ \underset{pre}{\uparrow} \ Bell_{D,P}^{\rightarrow}\left(2^{\omega}\right).$ 

**Definition 10.** A space X is Eberlein compact if it embeds in  $\Sigma^*\mathbb{R}^{\kappa} = \{x \in 2^{\kappa} : |\{\alpha : |x(\alpha)| \geq \epsilon\}| < \omega \text{ for all } \epsilon > 0\}.$ 

Theorem 11.  $\mathscr{Q} \underset{mark}{\uparrow} Bell_{D,P}^{\rightarrow} (\Sigma^{\star} \mathbb{R}^{\kappa}).$ 

*Proof.* Let  $\operatorname{supp}_{\epsilon}(x) = \{\alpha : |x(\alpha)| \geq \epsilon\} \in [\kappa]^{<\omega}$ . Let  $D_{\epsilon}$  be the entourage of the diagonal formed by balls of radius  $\epsilon$ . Finally, for  $z \in \mathbb{R}$  and  $n < \omega$ , let

$$\epsilon(z,n) = \min\left(\frac{1}{2^n}, \frac{|z|}{2}\right)$$

noting in particular that if  $|z| \ge \frac{1}{2^n}$ , then for any z' with  $|z'-z| < \epsilon(z,n)$ , it follows that  $|z'| \ge \frac{1}{2^{n+1}}$ .

Define the mark  $\sigma$  for  $\mathcal{D}$  such that

$$\sigma(\langle x \rangle, n) = \bigcap \{ P_{\alpha}(D_{\epsilon(x(\alpha), n)}) : \alpha \in \operatorname{supp}_{2^{-n}}(x) \}$$

Fix a legal attack  $p: \omega \to \Sigma^*\mathbb{R}^{\kappa}$ , and let  $\alpha < \kappa$ . If  $p_{\alpha}: \omega \to \Sigma^*\mathbb{R}^{\kappa}$  defined by  $p_{\alpha}(n) = p(n)(\alpha)$  converges for each  $\alpha < \kappa$ , then  $\sigma$  is a winning mark. So assume  $|p_{\alpha}(n)| \ge \frac{1}{2^n}$  for some n, and as  $\alpha \in \text{supp}(p(n))$ ,  $\sigma(p(n)) \subseteq P_{\alpha}(D_{\epsilon(p_{\alpha}(n),n)})$ . As p is a legal attack, it follows that  $|p_{\alpha}(n+1) - p_{\alpha}(n)| < \epsilon(p_{\alpha}(n),n)$ , and therefore  $|p_{\alpha}(n+1)| \ge \frac{1}{2^{n+1}}$ .

Thus  $|p_{\alpha}(m)| \geq \frac{1}{2^m}$  for all  $m \geq n$ , and as  $\alpha \in \text{supp}(p(m))$ ,  $\sigma(p(m)) \subseteq P_{\alpha}(D_{\epsilon(p_{\alpha}(m),m)})$ . As p is a legal attack, it follows that  $|p_{\alpha}(m+1) - p_{\alpha}(m)| < \epsilon(p_{\alpha}(m),m) \leq \frac{1}{2^m}$ , and therefore  $p_{\alpha}$  is a Cauchy sequence and converges.

Otherwise 
$$p_{\alpha}(n) < 2^{-n}$$
 for all  $n$ , so  $p_{\alpha}$  converges to 0.
